**kwargs

Keyword arguments (kwargs for short) are used to identify the argument by name, regardless of the position in which they are passed to your function. If their quantity is not known in advance, the **kwargs parameter is used, which groups them in a dictionary.

*As for *args, the name **kwargs is not mandatory but is suggested as good practice. Any name starting with ** will refer to these variable quantity arguments.*

```python
def person_attributes(**kwargs):
```

```python
person_attributes(eyes="blue", hair="short")
```

kwargs = {'eyes': 'blue', 'hair': 'short'}
